Introduction

Captchas is widely used to authenticate users, which plays an important role in Internet security, and conglutination characters segmentation is still the bottleneck of captcha recognition research.

The problem needed to solved in the captchas recognition

- Removing interfering background.
- Segmentation
- Captchas recognition

    B --> M[Segmentation of<br/>high<br/>conglutination<br/>characters<br/>->]
    H --> N[Extract character<br/>reference template<br/>->]
    H --> O[Character<br/>recognition<br/>->]
  
```

The flowchart illustrates the CAPTCHA recognition process. It begins with 'Read captcha image', followed by 'Graying'. From 'Graying', the process branches into several parallel steps: 'Circle detection—Hough transform algorithm', 'Remove interference circle—reverse color inside circle', 'Denoising—median filtering algorithm', and 'Binarization'. These steps converge into 'Character segmentation—vertical projection'. This step then branches into 'Automatic captcha recognition—template matching' and four parallel identification steps: 'Identify the conglutination type', 'Segmentation of low conglutination characters', 'Segmentation of part conglutination characters', and 'Segmentation of high conglutination characters'. 'Automatic captcha recognition—template matching' leads to 'Extract character reference template' and 'Character recognition'. Finally, 'Character recognition' leads to 'Get recognition result'.

Preprocess

- Background interference are the black circles.
- The characters are the mixture of capital English letters and Number
- No distortion or irregular
- The width of letters and number are different
- Some conglutination

Preprocess

- ## Preprocess

 - Background interference are the black circles.
 - The characters are the mixture of capital English letters and Number
 - No distortion or irregular
 - The width of letters and number are different
 - Some conglutination

Preprocess

step

- Using Gaussian blur preprocess image
- Remove circular interference based on hough algorithm
- Denoise by median filtering algorithm
- Binarization

Preprocess

Conglutination Example

- No conglutination

Improved Vertical Projection

- Identify the conglutination type
 - No conglutination
 - Edge tangent conglutination
 - Edge horn conglutination
- Segmentation of conglutination characters

Conglutination Example

- High conglutination

Conglutination Example

- Edge tangent conglutination and edge horn conglutination

Segmentation

Segmentation

Segmentation Steps

- Add up image 0-1 matrix by column and get a 1D array $col[]$.
- Traverse col and record the index of value 0 to $p[]$.
- Traverse p , do $p[j]-p[j-1]$ and compare with character width d .
- If $p[j]-p[j-1]<d$, two points in same blank area.
- If $d<p[j]-p[j-1]<2d$, $p[j]$ and $p[j-1]$ are the segmentation point of not conglutination characters.

Segmentation

Segmentation Steps cont.

- If $p[j]-p[j-1]>2d$, exists two characters in this area.
 - Iterate through $col[i]$ (i in $(p[j-1], p[j])$), find the max value of $col[i]$, then do $i-p[j-1]$, compare this value with d , if they are nearly equal, i will be the segmentation point of edge tangent conglutination characters.

Segmentation

Segmentation Steps cont.

- If $p[j]-p[j-1]>2d$, exists two characters in this area.
 - Iterate through $col[i]$ (i in $(p[j-1], p[j])$), find the min value of $col[i]$, then do $i-p[j-1]$, compare this value with d , if they are nearly equal, i will be the segmentation point of edge horn conglutination characters.
 - If not two cases above, cut in the middle of the area.

Recongnation

Recognition Steps

- Build cnn model and train with data set which obtained through preprocessing and segmentation with no fragmentary, no noise and no interference.
- Predict with trained model.
